

**VACCINES
ARE NOT
PLACEBO
SAFETY
TESTED**

All medications are safety tested using a placebo control group. This means that one group of patients receives the medication being safety tested while another group receives a placebo (an inert substance that has no effect on the body). Both groups of patients are tracked and compared for adverse reactions following the administration of the medication and the placebo substance. "Safety testing" for vaccines DOES NOT use a true placebo control. Treatment groups in vaccine trials receive the vaccine, while control groups receive previously licensed vaccines or the adjuvant solution (neither of which are inert substances). Administration of the same ingredients in both groups can easily mask adverse reactions and therefore cannot accurately prove safety.
